Decompile dll file to source code online

Decompile .net dll file to source code online. Decompile c# dll file to source code online.

this is the home page of (still another) open source machine code decompiler project. the goal of a decompiletor machine code is to analyze executable files (such as .exe or .dll files in windows or elf files in unix-like environments) and try to create a high-level representation of the machine code in executable file: the decompiler attempts to reconstruct the source code from which the executable was compiled first. to download the decompiler, go to the project page: since compilation is a non-reversible process (information such as comments and types of variable data is irreparably lost,) decompilation can never fully recover the source code of an executable machine code. However, with some timely assistance (read "" human.) can make a long way to this goal. an oracle can provide type of function parameters, otherwise unreachable code positions and user-specific comments. the decompiletor is designed to be a processor and agnostic platform. the intent is that you should be able to oat it to decompile executables for any architecture of the processor and not be tied to a particular set of instructions. Although currently only a x86 front-end is implemented, there is nothing that prevents you from implementing a front of 68k, sparc or vax if you need it. the decompiler can be executed as a command line tool, in which case it can be powered with a simple executable file or a decompiler project file, which not only specifies the executable file to decompile but also any oracular information that assists its work. the decompiler also has a graphic front-end, which allows an operator to specify the oracular information while examining the decompiled executable. decompiler ocitis are a source code file c containing all the removable code and a header file where you can find the type of reconstructed data. design the decompiler is composed of several stages. the loading phase loads the executable in memory and determines what type of executable is decompiled. the executable format usually defines the processor format and the environment of the expected operating system. for previous formats, such as MS-DOS files from MS-DOS, processor (real x86 mode) and operating system environment (MS-DOS) are implicit. Once the format is determined, the track is loaded into memory (understanding if necessary) and the pointer or segment relocations are executed. These relocations are also useful in successive phases of the decompiler, since each relocated pointer value can be assigned a preliminary a pointer and each segment selector relocated the type segmn selector; the scanning phase follows the loading phase. the executable will usually have one or more input points, addresses pointing to the executable code. the code on the input points is disassembled and tracked, looking in particular for the branches, the call and returns. Afterwards, individual procedures are discovered and the call chart has been accumulated, whose edges are called between procedures, the rewriting phase rewrites all the machine's specific instructions in instructions independent of the low-level machine. Idiomatic instruction sequences are rewritten to expressions. from this point onwards, the decompilation process is independent of the processor. the analysis phase first is an analysis of definitions of interprocedural attainment. This is done to determine, for each proc procedure of the program, that the registers of the processor are preserved and whichof the processor are modified after a proc call. A subsequent analysis of interpreter vittimism, combined with the results of the analysis of the definitions of achievement, determines that the registers of the processor are used as parameters and registers of the return value for each procedure. Note that this analysis avoids depending on a specific ABI processor / platform or calling convention. Once the two interproceural analyses are completed, the procedures can be rewritten with their explicit arguments. explicit.The analysis is then carried out on a procedural basis by procedure. Procedures are converted to SSA Form, state code flags are deleted and expressions are simplified. Finally, the procedures are converted from the SSA module. The interproceural type analysis phase attempts to recover the types of data used in the program by analyzing how the values are used by the program code, incorporating clues obtained from the transfer data and any oracular information provided by the user. Memory access expressions are converted into their equivalent C: pointer dereferences *(foo,) member access expressions (foo->bar,) and array references (foo[bar:]) Finally, a structure analysis rewrites the control structures from the goto-spaghetti code not structured to the C language if, while- / do-loops, and switching states. Development The decompiler is written in C# and currently addresses the CLR 2.0 version It is currently developed with Visual Studio 2005, but is the plan to have a MonoDevelop (wanna pitch in) work project soon? The project implements the Test Driven development methodology, with a heavy emphasis on unit testing. No new code is allowed in the project unless you have one or more associated tests written for it. Developing a decompiler is notoriously difficult work with a lot of special cases. Not having unit tests would make the development an eternal bug hunt as fixes for a bug introduce other bugs. Unit tests are developed using NUnit v2.2. The subversion is used for source control. State The decompiler project is in pre-alpha stage. As it stands, it is able to load MS-DOS and PE binary files, disassemble their content, rewrite the disassembled instructions in intermediate code, and perform the above mentioned analysis phase. Currently the work is focused on type analysis, while code structuring is on the back-burner as it is considerably less complex than type recovery.
