# How to shrink the size of a pdf on mac

How to shrink the size of a pdf on mac. How to shrink pdf file size on mac. How to shrink the size of a jpeg on mac.

I have a 15-inch Retina MacBook (2016, used Dj™). Whenever I take a screenshot, usually capture a PNG with 2-4MB of size. Although storage is always cheaper nowadays, for its purpose, having 2-4MB screenshots are, in my opinion, still overkill. It could be smaller. Especially if you use these screenshots in an online storage (they will cost \$\$!). If I can reduce a 2MB image of 90%, I can store ten times as many more images! In this article, share simple tips / tricks to reduce the size of my screenshot images. Even if you don't use Mac, this item should largely be relevant to you - in order to continue reading! ImageMagick The main ingredient to accomplish this is a tool called ImageMagick The fastest way to install is to use HomeBrew: If you have a Windows or Linux machine, or if you have Mac, but you want to download out of Homebrew, check the imageMagick download page! Convert image with magic image image Magick has a long list of bees. When you have time, I strongly encourage you to read what can be done. By default, MacBook A full-screen screenshot has a size of about 2000 x 3000 px. Usually, half of that size is enough. To reduce the image size, we can use the imageMagick conversion command. To convert a 50% image, run: Convert My-Screenshot.png -Resize 50% My-Resized-Screenshot.png The -Resize 50% option resize the entry image of 50%. Trial! Take a screenshot of the current window with CMD + SHIFT + 4 then press space. Click on the window you want to take a screenshot. In my case, the resulting screenshot is 2.1MB and has a size of 3548 x 2030. It's great! The execution of the convert command above reduces the size to 1792 x 1015. The file size is also reduced to around 430kb. This is a 80% reduction for a short line command! Some of you may think that 50% is too small - if this is the case, they feel free to play with the resize option. A good starting point is ImageMagick's resizing documentation: Resize or scale (general techniques). Pngquant Reduce an image from 2MB to 400KB is already a significant improvement. However, we can do more. We can make a loss compression of our image. This is a work for pngquant. Although ImageMagick also performs a compression of the images, I prefer to use pngquant because it has a cleaner API and produces a better output of ImageMagick (Disclaimer: actually I didn't spend a long time with Imagemagick's compression tools - take my word with A heavy salt granule and experimenting around ImageMagick compression tools yourself!) download PNGQuant with homebrew: PNGQuant Compression By default, screenshots taken from my Mac are PNG files, and then it works directly from the box. To compress an image, please do: I prefer to add some extra security, so my preferred command is: pngquant --skip-if-larger --forza --ext=.png MIAGGIO.png The --skip-if-larger option skips the image compression process if the resulting image is larger than the input image. L. L. always run PNGQuant with this option. The --ext=.png creates an image whose extension is a png. By default, PNGQuant creates an output filename ending with -fs8.png. This option prevents this. Force-force works in conjunction with --ext. Without force, the above command will complain that the file name already exists. With force, pngquant will overwrite the image with the compressed version. The --force --ext=.png command technically modifies the image. If you prefer to keep the original copy of the image, simply remove the --force --ext=.png options. You can run the PNGQuant command on your own against a newly captured screenshot or a resized screenshot. If you choose to run both ImageMagick and PNGQuant commands together, run the ImageMagick command first. If you run the PNGQuant first followed by the ImageMagick command, you may end up with a less compressed image. By putting together and creating a Bash Command inside my .bashrc / .zshrc / anything, I created this mini utility function: minimg () { echo "Resizing \$1" convert \$1 -resize 50% \$1 pngquant --skip-if-larger --force --ext=.png \$1 echo "Done!" } Don't forget to save and generate the file. With this, I can only do this to resize the image and compress it: On average, this reduces a screenshot image from 2MB to about 150KB, a reduction of 92.5%. Not bad! Extra: take screenshots and resize the image If you prefer to execute everything from the terminal, you can modify the function to include the screencapture command: screencap () { echo "Screencapturing" .. screenshot=\$ (che screencapture) \$screenshot -i \$1 if test -f "\$1" ; then eco "Resizing \$1" convert \$1 -resize 50% \$1 pngquant --skip-if-larger --force --ext=.png \$1 echo "Done!" fi } The screencapture command above is equivalent to Mac Cmd + Shift + 4. For example, to take a screen capture from CLI: screencapture -I echo cheese.png After executing this command, note that the cursor turns into a crosshair screencapture (if you press Space in this mode, it turns into a window screen capture). With this feature, you can take a screenshot, resize it, then compress it. Here. Here's how I resize my screenshots. I hope you are now able to take much lower resolution screenshots and make better use of your local/cloud storage. More importantly, now that you have smaller screenshots, they will be easier to carry around. Plus you get to learn a little bit of image editing. I think it's a win.
